Adobe Presenter 9 Download Crack For Idm..The invention relates to a device for rapid expansion of a gas to be used in equipment such as is employed in semiconductor manufacturing installations and for others. In particular, the invention relates to an aluminum bulb which is rapidly expanded to a pressure of about 150 atmospheres or higher. Thin film technology, including, for example, the production of MOSFET transistors and other devices such as vertical bipolar transistors and IGFETs, requires a number of processes which are conducted at high pressures. One of these processes involves the thermal annealing of the semiconductor wafer or substrate on which the MOSFET is to be fabricated, particularly that of a silicon wafer. The silicon wafer is heated to a temperature of about 1000.degree. C. to about 1200.degree. C. in an atmosphere of hydrogen for an extended period of time, typically from several seconds to a few minutes, while a voltage is applied across the wafer. The wafer thus placed in a high vacuum atmosphere serves as a cathode. The wafer is electrically isolated from the vacuum chamber wall with a positive electrical contact being made between the wafer and a flat metal anode that is mounted within the vacuum chamber. (Because the term "electrode" as used herein includes both cathodes and anodes, it will be understood that all electrodes are to be considered as anodes in this specification.) An electric current is passed between the wafer and the anode. As the wafer is heated, it begins to release electrons. These electrons bombard and erode the silicon anode. The electrons are supplied by the wafer cathode. During the annealing process, the pressure in the semiconductor wafer vacuum chamber is typically as high as 150 atmospheres. Furthermore, the anneal is typically conducted at temperatures which are as high as 1200.degree. C. (2272.degree
